Internet Printing Protocol/1.0: Protocol Specification
draft-ietf-ipp-protocol-00.txt

Status of this Memo

This document is an Internet-Draft. Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress".

To learn the current status of any Internet-Draft, please check the "Iid-abstracts.txt" listing contained in the Internet-Drafts Shadow Directories on ftp.is.co.za (Africa), nic.nordu.net (Europe), munnari.oz.au (Pacific Rim), ds.internic.net (US East Coast), or ftp.isi.edu (US West Coast).

Abstract

This document is one of a set of documents, which together describe all aspects of a new Internet Printing Protocol (IPP). IPP is an application level protocol that can be used for distributed printing using Internet tools and technology. The protocol is heavily influenced by the printing model introduced in the Document Printing Application (ISO/IEC 10175 DPA) standard. Although DPA specifies both end user and administrative features, IPP version 1.0 is focused only on end user functionality.

The full set of IPP documents includes:

- Internet Printing Protocol: Requirements
- Internet Printing Protocol/1.0: Model and Semantics
- Internet Printing Protocol/1.0: Security
- Internet Printing Protocol/1.0: Protocol Specification
- Internet Printing Protocol/1.0: Directory Schema

The requirements document takes a broad look at distributed printing functionality, and it enumerates real-life scenarios that help to clarify the features that need to be included in a printing protocol for the Internet. It identifies requirements for three types of users: end users, operators, and administrators. The requirements document calls out a subset of end user requirements that MUST be satisfied in the first version of IPP. Operator and administrator requirements are out of scope for v1.0. The model and semantics document describes a simplified model with abstract objects, their attributes, and their operations. The model introduces a Printer object and a Job object. The Job object supports multiple documents per job. The security document covers potential threats and proposed counters to those threats. The protocol specification is formal document which incorporates the ideas in all the other documents into a concrete mapping using clearly defined data representations and transport protocol mappings that real implementers can use to develop interoperable client and server side components. Finally, the directory schema document shows a generic schema for directory service entries that represent instances of IPP Printers.

This document is the "Internet Printing Protocol/1.0: Protocol Specification" document.

78 1. Introduction

79 This document contains the rules for encoding IPP operations and describes two layers: the transport layer and the operation
80 layer.

81 The transport layer consists of an HTTP/1.1 request or response. RFC 2068 [27] describes HTTP/1.1. This document specifies
82 the HTTP headers that an IPP implementation supports.

83 The operation layer consists of a message body in an HTTP request or response. The document "Internet Printing
84 Protocol/1.0: Model and Semantics" [21] defines the semantics of such a message body and the supported values. This
85 document specifies the encoding of an IPP operation. The aforementioned document is henceforth referred to as the "IPP model
86 document"

87 2. Conformance Terminology

88 The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT",
89 "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [25].

90 3. Encoding of the Operation Layer

91 The operation layer SHALL contain a single operation request or operation response.

92 The encoding is defined using both a diagram and Augmented Backus-Naur Form (ABNF), as specified by draft-ietf-drums-
93 abnf-02.txt [29] except that 'strings of literals' SHALL be case sensitive. For example 'A' means upper-case 'A' and not lower
94 case 'a'. In addition, two-byte binary signed integer fields are represented as '%x' values which show their range of values.

95 All binary integers in this encoding SHALL be transmitted in big-endian format (also known as "network order" and "most
96 significant byte first")

97 3.1 Syntax of Encoding

98 The encoding consists of four parts:

- 99 • version
- 100 • operation (for a request) or status (for a response)
- 101 • parameters
- 102 • data (which is optional)

103 The 'parameters' consists of a sequence of one or more 'parameter's. Each 'parameter' consists of:

- 104 • name-length: a two byte binary integer which is the length of the following 'name'
- 105 • name
- 106 • value-length: a two byte binary integer which is the length of the following 'value'
- 107 • value

108 There are 3 values for name-length with special meanings that provide for structuring of 'parameter's.

- 109 • 0 (0x0000): denotes an additional value for the preceding parameter. The following name is empty. That is, the
110 'value-length' starts in the next octet. A 'parameter' with this value consists of only a 'name-length', 'value-length'
111 and 'value'.
- 112 • -1 (0xFFFF): denotes the end of the 'parameters'. That is, the 'data' starts in the next octet. These 2 octets are present
113 even when there is no 'data'. A 'parameter' with this value consists of only a 'name-length'.
- 114 • -2 (0xFFFE): denotes the end of a 'parameter-group'. That is, the next 'parameter-group' starts in the next octet. This
115 special value exists only when an operation contains 2 or more 'parameter-groups'. Parameters are grouped to
116 separate operation parameters from object attributes and to separate attributes of one object from those of another
117 object. A 'parameter-group' is defined in greater detail in section 3.7 "Mapping of Attribute and Parameter Names".
118 A 'parameter' with this value consists of only a 'name-length'.

119 The syntax for the operation layer below shows the structure created by the 3 special 'name-length' values described above. -is:

```

120 ipp-message = ipp-request / ipp-response
121 ipp-request = version operation parameters %xFF %xFF[ data ]
122 ipp-response = version status parameters _%xFF %xFF[ data ]
123 version = major-version minor-version
124 major-version = SIGNED-BYTE ; initially %d1
125 minor-version = SIGNED-BYTE ; initially %d0
126 operation = SIGNED-SHORT ; mapping from model defined below
127 status = SIGNED-SHORT ; mapping from model defined below
128 parameters = parameter-group *(END-PARAMETER_GROUP%xFF %xFF parameter-group) END-PARAMETERS
129 parameter-group = *parameter-set
130 parameter-set = single parameter *(more-values)
131 single parameter = name-length name value-length value
132 more-values = ZERO-NAME-LENGTH value-length value
133 name-length = SIGNED-SHORT ; number of octets of 'name'
134 name = LALPHA *( LALPHA / DIGIT / "-" / "_" )
135 value-length = SIGNED-SHORT ; number of octets of 'value'
136 value = OCTET-STRING
137 zero name length = %x00 %x00
138 data = OCTET-STRING
139
140 ZERO-NAME-LENGTH = %x00 %x00 ; name-length of 0
141 END-PARAMETERS = %xFF %xFF ; name-length of -1
142 END-PARAMETER_GROUP = %xFF %xFE ; name-length of -2
143 SIGNED-BYTE = %x0..%xFF
144 SIGNED-SHORT = %x0..%xFF %x0..%xFF
145 DIGIT = "0".."9"
146 LALPHA = "a".."z"
147 BYTE = %x0..%xFF
148 OCTET-STRING = *BYTE
149

```

150 ISSUE: should there be a "type-of-value" byte so that a parser can decode a value without looking up the attribute name? If
151 there were such a byte, it could also server as the flag byte for the negative values, solving two problems with one byte per
152 parameter.

153 NOTE: there are 3 additional fields that are positioned, from a decoding view, in the same position as the 'name-length' field.
154 These fields are defined in the syntax above, and they have the following 3 special values:

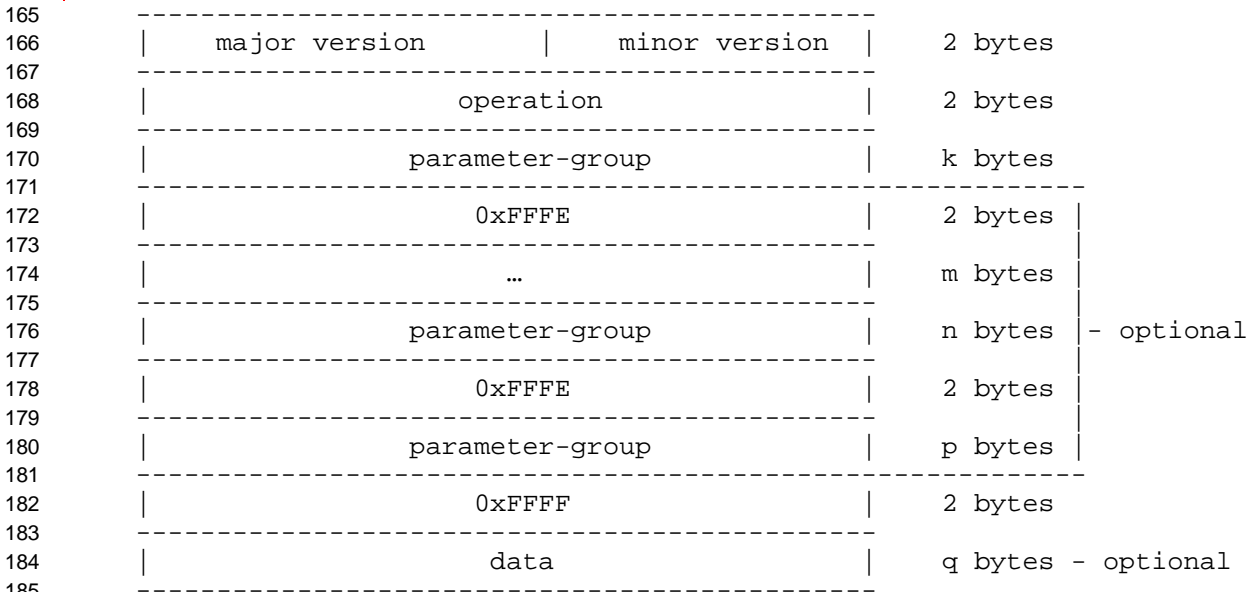

- 155 • 0 (0x0000): denotes an additional value of a parameter. When a parameter has more than one value, the parameter-
156 name for all but the first value is empty and has a length of zero.

- 157 | ~~1 (0xFFFF): denotes the end of the parameters. The 'data' starts in the next byte. The 2 bytes of 1 are present even~~
- 158 | ~~when there is no data.~~
- 159 | ~~2 (0xFFFE): denotes the end of a parameter group. The next parameter group starts in the next byte. This special~~
- 160 | ~~value exists only when an operation contains 2 or more parameter groups. A parameter group is defined in greater~~
- 161 | ~~detail in section 3.7 "Mapping of Attribute and Parameter Names".~~

162 3.2 Diagram of Encoding

163 The following is a diagram of the encoding of a request operation.

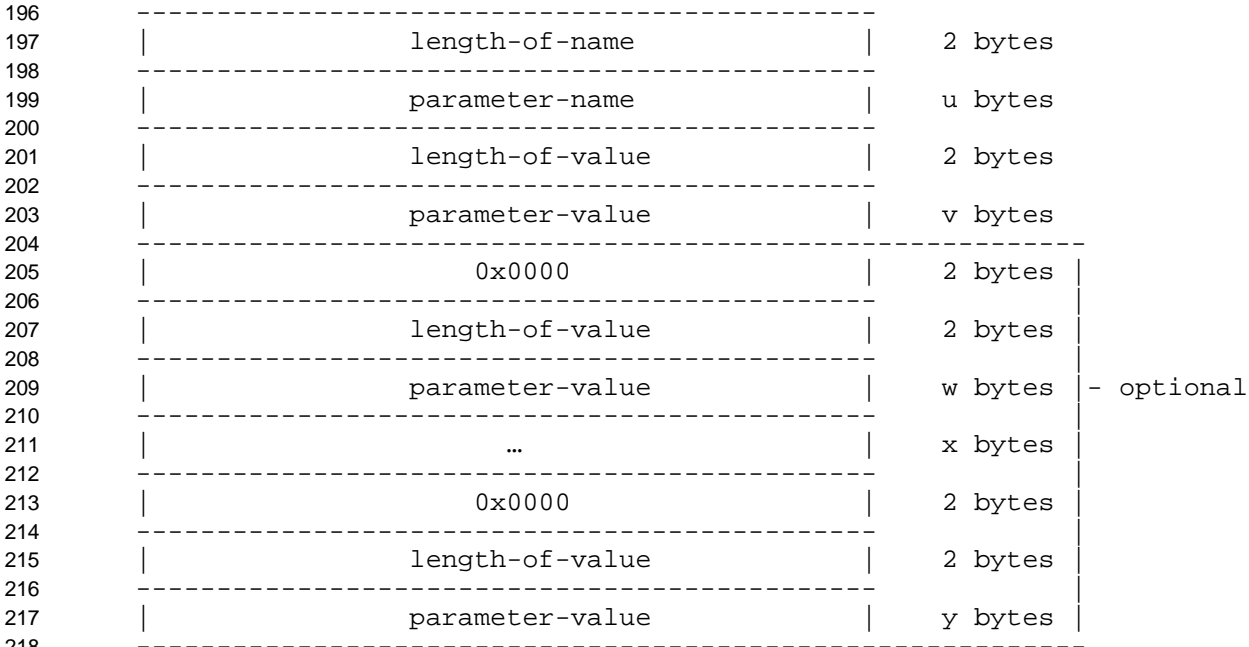

164 Note: ~~there are be~~ 1 or more 'parameter groups' may be omitted, and '-data' may be omitted.

187 The following is a diagram of the 'parameter-group' which is 0 or more 'parameter's

195 The following is a diagram of a `parameter`. The optional fields are present only when a `parameter` has more than one value.

220 The encoding of a response operation is identical to the encoding of a request operation except that the 'status' field SHALL
221 replaces the 'operation' field.

222 3.3 Version

223 The version SHALL consist of a major and minor version, each of which SHALL be represented by a one byte signed integer.
224 The protocol described in this document SHALL have a major version of 1 (0x01) and a minor version of 0 (0x00).

225 3.4 Mapping of Operations

226 The following SHALL be the mapping of operations names to integer values which are encoded as two byte binary signed
227 integers. The operations are defined in the IPP model document "Internet Printing Protocol/1.0: Model and Semantics".

| Operation | Integer Encoding (in decimal) |
|------------------|--------------------------------------|
| Get-Operations | <u>10</u> |
| Print-Job | <u>21</u> |
| Print-URI | <u>32</u> |
| Validate-Job | <u>43</u> |
| Create-Job | <u>54</u> |
| Send-Document | <u>65</u> |
| Send-URI | <u>76</u> |
| Cancel-Job | <u>87</u> |
| Get-Attributes | <u>98</u> |
| Get-Jobs | <u>109</u> |

228

229 3.5 Mapping of Status

230 The following SHALL be the mapping of status names to integer values which are encoded as two byte binary signed integers.
 231 The status names are defined in the [IPP model](#) document "~~Internet Printing Protocol/1.0: Model and Semantics~~".

232 If an IPP status is returned, then the HTTP status MUST be 200 (OK). With any other HTTP status value, the HTTP response
 233 SHALL NOT contain an IPP message-body, and thus no IPP status is returned.

234 Note: the integer encodings below were chosen to be similar to corresponding status values in HTTP. But the status returned at
 235 the HTTP level will always be different except in the case where 'OK' is returned at both levels, 200 (OK) in HTTP and 0
 236 (successful-OK) in IPP.

237 Note: some status values, such as client-error-unauthorized, may be returned at the transport (HTTP) level rather than the
 238 operation level.

239 ISSUE: as implementations proceed, we will learn what error code need to be supported at the IPP level.

| Status Name | Integer Encoding (in decimal) |
|--|-------------------------------|
| successful-OK | 0 |
| client-error-bad-request | 400 |
| client-error-unauthorized | 401 |
| client-error-payment-required | 402 |
| client-error-forbidden | 403 |
| client-error-not-found | 404 |
| client-error-method-not-allowed | 405 |
| client-error-timeout | 408 |
| client-error-gone | 410 |
| client-error-request-entity-too-large | 413 |
| client-error-request-URI-too-long | 414 |
| client-error-unsupported-document-format | 415 |
| client-error-attribute-not-supported | 416 |
| server-error-internal-server-error | 500 |
| server-error-operation-not-implemented | 501 |
| server-error-service-unavailable | 503 |
| server-error-timeout | 504 |
| server-error-version-not-supported | 505 |
| server-error-printer-error | 506 |
| server-error-temporary-error | 507 |

240 3.6 ~~Name Lengths of Parameter Names~~

241 Each parameter 'name' SHALL be preceded by a two byte binary signed integer in big endian order which SHALL specify the
 242 number of octets in the 'name' which follows this length, exclusive of the two bytes specifying the length.

243 The 'name-length' field SHALL consist of a two byte binary signed integer in big endian order. This field SHALL specify the
 244 number of octets in the 'name' which follows the name-length field, excluding the two bytes of the 'name-length' field.

245 If a 'name-length' field has a value of zero, the following 'name' field SHALL be empty, and the following value SHALL be
 246 treated as an additional value for the preceding parameter.

247 If a 'name-length' field as a negative value, it SHALL act as a separator field and the meaning of the following octets SHALL
 248 be as specified by the syntax above.

249 3.7 Mapping of ~~Attribute and~~ Parameter Names

250 ~~Attribute names and parameter names are ASCII text strings whose values SHALL be the text names defined in the document~~
251 ~~"Internet Printing Protocol/1.0: Model and Semantics".~~

252 ~~The document "Internet Printing Protocol/1.0: Model and Semantics" defines the parameters for each operation. Some of these~~
253 ~~parameters SHALL receive special handling in the protocol, as described below.~~

254 ~~The parameter named "status" for each response SHALL become the "status" field in the operation layer. A response may~~
255 ~~optionally include the parameter "reason-phase" to specify human-readable text associated with the status. If this parameter is~~
256 ~~in the response, it SHALL be the first one.~~

257 ~~The parameter named "document-content", which is defined for some requests, SHALL become the "data" in the operation~~
258 ~~layer.~~

259 ~~Requests and responses contain a mixture of parameters and attributes. All parameters SHALL be in the first parameter group.~~
260 ~~Attributes SHALL be in the second parameter group. If an operation returns attributes from more than one object (e.g. Get-~~
261 ~~Jobs), the attributes from each object SHALL be in a separate parameter group.~~

262 Some parameters are encoded in a special position. These parameters are:

- 263 • "target URI": The target URI of each operation in the IPP model document SHALL be specified outside of the
264 operation layer and SHALL not be specified within the operation layer.
- 265 • "document-content": The parameter named "document-content" in the IPP model document SHALL become the
266 "data" in the operation layer.
- 267 • "status": The parameter named "status" in the IPP model document SHALL become the "status" field in the operation
268 layer response. A response may optionally include the parameter "reason-phase" to specify human-readable text
269 associated with the status. A client MAY display such text to an end-user and a server MAY return such text in the
270 language requested by the client. If this parameter is in the response, it SHALL be the first one in the first parameter-
271 group.

272 ISSUE: Should the target-URI be outside the operation layer?

273 The remaining parameters are encoded in one of the parameter-groups. The first parameter group is for actual operation
274 parameters and subsequent parameter-groups are for object attributes. Of the parameters defined in the IPP model document,
275 some represent an actual operation parameters and others represent a collection of object attributes.

276 A parameter in the IPP model document SHALL represent a collection of object attributes if it contains the word "attributes" in
277 its name with no hyphen before "attributes" ; otherwise it SHALL represent an actual operation parameter.

278 ISSUE: need to align a few names in the IPP model document to make this rule be correct.

279 If a parameter in IPP model document represents an actual operation parameter and is not in a special position, it SHALL be
280 encoded in the first parameter-group using the text name of the parameter specified in the IPP model document.

281 If a parameter in IPP model document represent a collection of object attributes, the attributes SHALL be encoded in the second
282 or subsequent parameter-groups using the text names of the attributes specified in the IPP model document. The IPP model
283 document specifies the members of such attribute collections, but does not require that all members of a collection be present in
284 an operation.

285 If an operation contain attributes from exactly one object, there SHALL be a second parameter-group, but no additional ones. If
286 an operation contains attributes from more than one object (e.g. Get-Jobs response), the attributes from each object SHALL be

287 in a separate parameter-group, such that the attributes from the first object are in the second 'parameter-group', the attributes
 288 from the second object are in the third 'parameter-group', etc.

289 The next three tables show the results of applying the rules above to the operations defined in the IPP model document.

290 The following table shows the mapping of all request parameters (except target URI) to a parameter-group or special position in
 291 the protocol, as described in the IPP model document.

| <u>Operation</u> | <u>first parameter-group</u> | <u>second parameter-group</u> | <u>special position</u> |
|-------------------------|-------------------------------------|--------------------------------------|--------------------------------|
| <u>Get-Operations</u> | | | |
| <u>Print-Job</u> | | <u>job-template attributes</u> | <u>document-content</u> |
| <u>Validate-Job or</u> | | <u>job-template attributes</u> | |
| <u>Create-Job</u> | | | |
| <u>Print-URI</u> | <u>document-uri</u> | <u>job-template attributes</u> | |
| <u>Send-Document</u> | <u>last-document</u> | <u>document attributes</u> | <u>document-content</u> |
| <u>Send-URI</u> | <u>last-document</u> | <u>document attributes</u> | |
| | <u>document-uri</u> | | |
| <u>Cancel -Job</u> | <u>message</u> | | |
| | <u>reply-with-status (?)</u> | | |
| <u>Get-Attributes</u> | <u>document-format</u> | | |
| | <u>requested-attributes</u> | | |
| <u>Get-Jobs</u> | <u>limit</u> | | |
| | <u>requested-attributes</u> | | |

292

293 The following table shows the mapping of all response parameters to a parameter-group or special position in the protocol, as
 294 described in the IPP model document.

| <u>Operation</u> | <u>first parameter-group</u> | <u>second parameter-group</u> | <u>special position</u> |
|--------------------------|-------------------------------------|--------------------------------------|--------------------------------|
| <u>Get-Operations</u> | <u>supported-operations</u> | <u>reason-phrase</u> | <u>status</u> |
| <u>Print-Job, Print-</u> | <u>job-uri</u> | <u>reason-phrase</u> | <u>status</u> |
| <u>URI or Create-Job</u> | | <u>job-status attributes</u> | |
| <u>Send-Document or</u> | | <u>reason-phrase</u> | <u>status</u> |
| <u>Send-URI</u> | | <u>job-status attributes</u> | |
| <u>Validate-Job</u> | | <u>reason-phrase</u> | <u>status</u> |
| <u>Cancel-Job</u> | | <u>reason-phrase</u> | <u>status</u> |
| | | <u>job-status attribute ?</u> | |
| <u>Get-Attributes</u> | | <u>reason-phrase</u> | <u>status</u> |
| | | <u>requested attributes</u> | |
| <u>Get-Jobs</u> | | <u>reason-phrase</u> | <u>status</u> |
| | | <u>requested attributes</u> | |
| | | <u>(see the Note below)</u> | |

295

296 Note for Get-Jobs: there is a separate 'parameter-group' containing requested-attributes for each job object in the response

297 The following table shows the mapping of all error response parameters to a parameter-group or special position in the
 298 protocol, as described in the IPP model document. Those operations omitted don't have special parameters for an error return.

| | | | |
|------------------|------------------------------|-------------------------------|-------------------------|
| <u>Operation</u> | <u>first parameter-group</u> | <u>second parameter-group</u> | <u>special position</u> |
|------------------|------------------------------|-------------------------------|-------------------------|

| | | | |
|--|-------------------------------|---------------|--|
| <u>Print-Job, Print-URI, Validate-Job, Create-Job, Send-Document or Send-URI</u> | <u>unsupported attributes</u> | <u>status</u> | |
|--|-------------------------------|---------------|--|

299

300 3.8 Value Lengths of Parameter Values

301 Each parameter value SHALL be preceded by a two byte binary signed integer in big endian order which SHALL specify the
302 number of octets in the value which follows this length, exclusive of the two bytes specifying the length.

303 3.9 Mapping of Attribute and Parameter Values

304 The following SHALL be the mapping of attribute and parameter values to their IPP encoding. The syntax types are defined in
305 the IPP model document, ~~"Internet Printing Protocol/1.0: Model and Semantics"~~.

| Syntax of Attribute Value | Encoding |
|---------------------------|----------|
|---------------------------|----------|

| | |
|-------------------|---|
| text | an octet string where each character <u>is a member of the UCS-2 coded character set and</u> is encoded <u>using in UTF-8. The text is encoded in "network byte order" with the first character in the text (according to reading order) being the the first character in the encoding. The first character in the octet string is the encoding of the first character in the text value</u> |
| name | same as text |
| fileName | same as text |
| keyword | same as text. Allowed text values are defined in the <u>IPP model</u> document "Internet Printing Protocol/1.0: Model and Semantics" . |
| uri | same as text |
| uriScheme | same as text |
| locale | same as text |
| boolean | one binary octet where 0x00 is 'false' and 0x01 is 'true' |
| integer | number of octets is a power of 2 (i.e. 1, 2 or 4). These octets represent a signed binary integer in big endian order (<u>also known as "network byte order" and MSB first</u>). |
| enum | same as integer. Allowed integer values are defined in the <u>IPP model</u> document "Internet Printing Protocol/1.0: Model and Semantics" . |
| dateTime | same as text. Syntax of data and time is defined by ISO 8601 ISSUE: should ISO 8601 be called out in the <u>IPP</u> model document? |
| seconds | same as integer |
| milliseconds | same as integer |
| 1setOf X | encoding according to the rules for a parameter with more than more value. Each value X is encoded according to the rules for encoding its type. |
| rangeOf X | same 1setOf X where the number of values is 2. |

306

307 There is sometimes a need for a parameter to have some special 'out-of-band' values. Such value are represented by empty
 308 values with special negative lengths as specified by the table below.

| Special Value | Value of Value-length |
|---------------|-----------------------|
| default | -1 |
| unsupported | -2 |

309

310 If a response contains a parameter of "unsupported attribute", the value of "unsupported" shall be used to denote that the
 311 Printer does not support the attribute.

312 ISSUE: The above sentence belongs in the IPP model document.

313 3.10 ~~Encoding of~~ Data

314 ~~No encoding SHALL be applied to the data. The data SHALL be~~ It is included within the operation as is. For print operations
 315 where the data is document data, this data consists of the identical octet-string that the client specified to print.

316 NOTE: In HTTP, however, the data may be encoded as part of the ~~allows an encoding of to be applied to~~ the entire message-
 317 body.

318 4. Encoding of Transport Layer

319 HTTP/1.1 shall be the transport layer for this protocol.

320 The operation layer has been designed with the assumption that the transport layer contains the following information:

- 321 • the URI of the target job or printer operation
- 322 • the total length of the data in the operation layer, either as a single length or as a sequence of chunks each with a
 323 length.
- 324 • the client's language, the character-set and the transport encoding.

325 Each HTTP operation shall use the POST method where the URI is the object target of the operation, and where the "Content-
 326 Type" of the message-body in each request and response shall be "application/ipp". The message-body shall contain the
 327 operation layer and shall have the syntax described in section 2 "Conformance Terminology".

328 ISSUE: Should the URI of the operation be in the operation layer? Should the URI in the POST be a server/printer always with
 329 the target object as a parameter within the message-body?

330 In the following sections, there are a tables of all HTTP headers which describe their use in an IPP client or server. The
 331 following is an explanation of each column in these tables.

- 332 • the "header" column contains the name of a header
- 333 • the "request/client" column indicates whether a client sends the header. ~~The values in each cell are described below:~~
- 334 • the "request/server" column indicates whether a server supports the header when received. ~~The values in each cell are~~
 335 ~~described below.~~
- 336 • the "response/server" column indicates whether a server sends the header. ~~The values in each cell are described below:~~
- 337 • the "response /client" column indicates whether a client supports the header when received. ~~The values in each cell are~~
 338 ~~described below.~~

- 339 • the “values and conditions” column specifies the allowed header values and the conditions for the header to be present
340 in a request/response.

341 The table for “request headers” does not have columns for responses, and the table for “response headers” does not have
342 columns for requests.

343 The following is an explanation of the values in the “request/_client” and “response/_server” columns.

- 344 • man: (mandatory) the client or server **MUST** send the header,
345 • c-man: (conditionally mandatory) the client or server **MUST** send the header when the condition described in the
346 “values and conditions” column is met,
347 • opt: (optional) the client or server **MAY** send the header
348 • not: (not needed) the client or server **SHOULDNEED** NOT send the header. It is not relevant to an IPP
349 implementation.

350 The following is an explanation of the values in the “response/_client” and “request/_server” columns.

- 351 • man: (mandatory) the client or server **MUST** support the header,
352 • opt: (optional) the client or server **MAY** support the header
353 • not: (not needed) the client or server **SHOULDNEED** NOT support the header. It is not relevant to an IPP
354 implementation.

355 4.1 General Headers

356 The following is a table for the general headers.

357 ISSUE: an HTTP expert should review these tables for accuracy.
358

| General-Header | Request | | Response | | Values and Conditions |
|-------------------|---------|--------|----------|--------|---|
| | Client | Server | Server | Client | |
| Cache-Control | man | not | man | not | “no-cache” only |
| Connection | c-man | man | c-man | man | “close” only. Header MUST be present only for last request/response before the connection is closed. |
| Date | opt | opt | man | opt | per RFC 1123 [9] |
| Pragma` | man | not | man | not | “no-cache” only |
| Transfer-Encoding | c-man | man | c-man | man | “chunked” only . Header MUST be present if Content-Length is absent. |
| Upgrade | not | not | not | not | |
| Via | not | not | not | not | |

359

360 4.2 Request Headers

361 The following is a table for the request headers.

362

| Request-Header | Client | Server | Request Values and Conditions |
|-----------------|--------|--------|--|
| Accept | opt | man | “application/ipp” only. This value is the default if the client omits it |
| Accept-Charset | opt | man | per IANA Character Set registry. ISSUE: is this useful for IPP? |
| Accept-Encoding | opt | man | empty and per RFC 2068 [27] and IANA registry for content-codings |
| Accept-Language | opt | man | see RFC 1766 [26] |
| Authorization | c-man | man | per RFC 2068. A client sends this header when it receives a 401 |

| Request-Header | Client | Server | Request Values and Conditions |
|-----------------------|---------------|---------------|--|
| From | not | not | “Unauthorized” response and no “Proxy-Authenticate” header. per RFC 2068. Because RFC recommends sending this header only with the user’s approval, it is not very useful |
| Host | man | man | per RFC 2068 |
| If-Match | not | not | |
| If-Modified-Since | not | not | |
| If-None-Match | not | not | |
| If-Range | not | not | |
| If-Unmodified-Since | not | not | |
| Max-Forwards | not | not | |
| Proxy-Authorization | c-man | not | per RFC 2068. A client MUST send this header when it receives a 401 “Unauthorized” response and a “Proxy-Authenticate” header. |
| Range | not | not | |
| Referer | not | not | |
| User-Agent | not | not | |

363 4.3 Response Headers

364 The following is a table for the request headers.

365

| Response-Header | Server | Client | Response Values and Conditions |
|------------------------|---------------|---------------|---|
| Accept-Ranges | not | not | |
| Age | not | not | |
| Location | c-man | opt | per RFC 2068. When URI needs redirection. |
| Proxy-Authenticate | not | man | per RFC 2068 |
| Public | opt | opt | per RFC 2068 |
| Retry-After | opt | opt | per RFC 2068 |
| Server | not | not | |
| Vary | not | not | |
| Warning | opt | opt | per RFC 2068 |
| WWW-Authenticate | c-man | man | per RFC 2068. When a server needs to authenticate a client. |

366 4.4 Entity Headers

367 The following is a table for the request headers.

368

| Entity-Header | Request | | Response | | Values and Conditions |
|----------------------|----------------|---------------|-----------------|---------------|--|
| | Client | Server | Server | Client | |
| Allow | not | not | not | not | |
| Content-Base | not | not | not | not | |
| Content-Encoding | opt | man | man | man | per RFC 2068 and IANA registry for content codings. see RFC 1766 [26]. |
| Content-Language | opt | man | man | man | |
| Content-Length | c-man | man | c-man | man | the length of the message-body per RFC 2068. Header MUST be present if Transfer-Encoding is absent.. |
| Content-Location | not | not | not | not | |
| Content-MD5 | opt | opt | opt | opt | per RFC 2068 |
| Content-Range | not | not | not | not | |
| Content-Type | man | man | man | man | “application/ipp” only |
| ETag | not | not | not | not | |

| Entity-Header | Request | | Response | | Values and Conditions |
|---------------|---------|--------|----------|--------|-----------------------|
| | Client | Server | Server | Client | |
| Expires | not | not | not | not | |
| Last-Modified | not | not | not | not | |

369

370 5. Security Considerations

371

372 When utilizing HTTP 1.1 as a transport for IPP, all of the security considerations specified in RFC 2068 [27] apply. In
 373 addition, the IPP adds some additional application-specific security considerations, including denial-of-service attacks, mutual
 374 authentication, and privacy. The IPP ~~m~~Model document addresses IPP-specific security considerations, while RFC 2068
 375 addresses HTTP-related security considerations.

376 ISSUE: the security subgroup is free to add whatever is necessary to fill out the "security considerations" section of this
 377 document. However, the IPP model document should include the bulk of security discussions that are IPP-specific.

378

379 6. Appendix A: Requirements with~~out Transports other than~~ HTTP/1.1 as a Transport Layer

380

381 ~~The operation layer defined above assumed certain services would be provided by the HTTP transport layer. Without that layer,~~
 382 ~~information, such as length, URI and Content-Encoding are absent. Some transports, such as raw TCP/IP, don't have a way to~~
 383 ~~specify length or carry along parameters supported by a transport layer, such as HTTP/1.1. An example of such a parameter is~~
 384 ~~the Content Encoding for an operation. Another example is the target URI.~~

385 This section specifies the modifications to the operation-layer encoding for ~~transports, such as~~ raw TCP/IP. The following
 386 changes would have to be made. All of these changes are upward compatible with the encoding defined in section 3 "Encoding of
 387 the Operation Layer".

388 6.1 Additional Parameter-group for HTTP header information

389 First there is an additional header parameter-group which SHALL appear as the first parameter-group, preceding the
 390 parameter-group for actual operation parameters, and which SHALL contain the "target_ URI" along with relevant HTTP
 391 header information, including those shown below. This header parameter-group SHALL be preceded by a name-length of -4
 392 (0xFFFC) which functions like the other negative lengths defined in section 3 "Encoding of the Operation Layer". This special
 393 number specifies that the first parameter group contains header type information, and distinguishes it from the protocol which
 394 has these parameters outside of the operation layer.

395 The following table shows the mapping of HTTP headers to parameters in the operation layer.

| HTTP header or other concept | IPP parameter name | Syntax Type of Parameter |
|------------------------------|--------------------|--------------------------|
| URI | target-URI | uri |
| Connection | Close-Connection | Boolean |
| Accept-Charset | Accept-Charset | keyword |
| Accept-Encoding | Accept-Encoding | keyword |
| Accept-Language | Accept-Language | keyword |
| Content-Encoding | Content-Encoding | keyword |
| Content-Language | Content-Language | keyword |

| HTTP header or other concept | IPP parameter name | Syntax Type of Parameter |
|------------------------------|-------------------------|--------------------------|
| charset parameter | Content-Charset | keyword |
| miscellaneous security | if needed at this level | |

396

397 The first parameter in the header parameter-group for a request SHALL be the attribute "target-URI" which is the target object
398 of the operation.

399 Except for Content-Encoding, the parameters SHALL take effect at the beginning of the next parameter-group and apply to the
400 rest of the operation. If the parameter is Content-Encoding, then the encoding SHALL apply only to the 'full-data' or 'data-
401 segment's as defined by the syntax below and the resulting decoded data SHALL have the syntax of "parameters data" as
402 defined by the syntax below. That is, from a decoding point of view if Content-Encoding is specified, the operation's data is
403 decoded using the algorithm specified by Content-Encoding. The resulting octet stream is parsed as if it were a 'parameters'
404 followed by 'data'.

405 NOTE: This rule for Content-Encoding allows a client or server to encode operation parameters or to transmit them unencoded.

406 ISSUE: should the reason-phrase be in the initial parameter group instead of the second one for responses?

407 6.2 Chunking of Data

408 Second the "parameters" and "data" of the operation layer are separated by -3 (0xFFFD) instead of -1 (0xFFFF) to denote that
409 the following data is chunked. A chunk of length 0 denotes the end of the data. The syntax for the chunked data is:

410 chunked-data = *data-chunk END-OF-DATA %x00 %x00
411 data-chunk = data-segment-length data-segment
412 data-segment-length = SIGNED-SHORT ; number of octets of the data in binary
413 data-segment = OCTET-STRING

414

415 END-OF-DATA = %x00 %x00

416

417 A data-segment contains fragments of the data. When all the data-segments are concatenated together, they form the complete
418 data.

419 6.3 Revised Syntax for the Operation Layer

420 The following is the revised syntax for the operation layer.

421 ipp-message = ipp-request / ipp-response
422 ipp-request = version operation parameters data
423 ipp-response = version status parameters %xFF %xFF [+data]
424 version = major-version minor-version
425 major-version = SIGNED-BYTE ; initially %d1
426 minor-version = SIGNED-BYTE ; initially %d0
427 operation = SIGNED-SHORT ; mapping from model defined below
428 status = SIGNED-SHORT ; mapping from model defined below
429 parameters = (headers / parameter-group) *(END-PARAMETER_GROUP %xFF %xFE parameter-group)
430 headers = START_HEADER %xFF %xFC parameter-group
431 parameter-group = *parameter
432 parameter = single-parameter *(more-values)
433 single-parameter = name-length name value-length value

```

434 more-values = ZERO-NAME-LENGTH value-length value
435 name-length = SIGNED-SHORT ; number of octets of 'name'
436 name = LALPHA *( LALPHA / DIGIT / "-" / "_" )
437 value-length = SIGNED-SHORT ; number of octets of 'value'
438 value = OCTET-STRING
439 zero-name-length = %x00 %x00
440 data = ( END-PARAMETERS %xFF %xFF [ full-data ] ) / ( END-PARAMETERS-CHUNKED %xFF %xFD chunked-data
441 )
442 full-data = OCTET-STRING
443 chunked-data = *data-chunk %x00 %x00
444 data-chunk = data-segment-length data-segment
445 data-segment-length = SIGNED-SHORT ; number of octets of the data in binary
446 data-segment = OCTET-STRING
447
448 ZERO-NAME-LENGTH = %x00 %x00 ; name-length of 0
449 END-PARAMETERS = %xFF %xFF ; name-length of -1
450 END-PARAMETER GROUP = %xFF %xFE ; name-length of -2
451 END-PARAMETERS-CHUNKED = %xFF %xFD ; name-length of -3
452 START HEADER = %xFF %xFC ; name-length of -4
453 SIGNED-BYTE = %x0..%xFF
454 SIGNED-SHORT = %x0..%xFF %x0..%xFF
455 DIGIT = "0".."9"
456 LALPHA = "a".."z"
457 BYTE = %x0..%xFF
458 OCTET-STRING = *BYTE

```
